

REMARKS

The specification is amended above to insert a reference to related cases and to correct typographical errors.

No amendment of inventorship is necessitated by these amendments.

Early allowance of the claims is requested. Should the Examiner believe that a conference with applicants' attorney would advance prosecution of this application, he is respectfully invited to call applicants' attorney.

Respectfully submitted,

Mark Chao, Ph.D., Reg. No. 37,293
Elaine M. Ramesh, Ph.D., Reg. No. 43032
Attorney for Applicants

4-i-Pr-Ph
4-i-Pr-Ph

connected in series. For example, the branch dedicated to user 1 illustrated in the upper part of the Fig. comprises a multiplier 310_1 for multiplying the complex value $\sqrt{P_{t_1}} \cdot d_1$ (it is recalled that d_1 is the symbol to be transmitted to user 1) with the spreading sequence $c_1(\ell)$, a demultiplexer 320_1 for serial-to-parallel converting the

5 spread complex values, a parallel multiplier 330_1 for multiplying each of the spread complex values $\sqrt{P_{t_1}} \cdot d_1 \cdot c_1(\ell)$ with components of a complex weighting vector \mathbf{w}_1^* as defined further below. The result of the parallel multiplication in 330_1 is represented by the M vectors $\mathbf{z}_1^1, \dots, \mathbf{z}_1^M$ each vector \mathbf{z}_1^m being constituted of the frequency components of the signal to be transmitted by the antenna 370_m . More specifically,

10 \mathbf{z}_1^m , $m=1, \dots, M$ is defined as a L -dimension vector $(z_1^m(1), \dots, z_1^m(L))^T$ where $z_1^m(\ell) = \sqrt{P_{t_1}} \cdot d_1 \cdot c_1(\ell) \cdot w_1^*(\ell, m)$. Similarly, the output of the parallel multiplier 330_k of the k^{th} branch is constituted of M vectors $\mathbf{z}_k^1, \dots, \mathbf{z}_k^M$ the elements of which are given by $z_k^m(\ell) = \sqrt{P_{t_k}} \cdot d_k \cdot c_k(\ell) \cdot w_k^*(\ell, m)$.

For a given user k the complex weighting coefficients $w_k^*(\ell, m)$ are grouped into

15 a vector \mathbf{w}_k of size $M \cdot L$ defined as $\mathbf{w}_k^* = (w_k^*(1,1), \dots, w_k^*(L,1), \dots, w_k^*(1,M), \dots, w_k^*(L,M))^T$, the first L elements of which corresponding to the weighting coefficients for antenna 1, user k and subcarriers 1 to L , the second L elements of which corresponding to the weighting coefficients for antenna 2, user k and subcarriers 1 to L , and so on. As the coefficients $w_k^*(\ell, m)$ are applied both in the space domain (for a given subcarrier

20 ℓ , they can be regarded as forming a beam for user k) and in the frequency domain (for a given antenna m , the coefficients $w_k^*(\ell, m)$ can be regarded as those of conventional frequency filter), the vector \mathbf{w}_k^* will be hereinafter referred to as the space-frequency transmit filtering (SFTF) vector associated to user k .

The MC-CDMA transmitter is further provided with a plurality M of adders

25 $340_1, \dots, 340_M$, each adder 340_m adding the signal vectors $\mathbf{z}_1^m, \dots, \mathbf{z}_K^m$, $m=1, \dots, M$ output by the parallel multipliers $330_1, \dots, 330_M$ and supplying the resulting vectors to the modules $350_1, \dots, 350_M$ respectively. More precisely, each module 350_m (identical to the module 130_k in Fig. 1) performs an inverse Fast Fourier Transform on the vector of compound frequency components $\left(\sum_{k=1}^K z_k^m(1), \dots, \sum_{k=1}^K z_k^m(L) \right)^T$ and adds a prefix (Δ) to the MC-

30 CDMA symbol thus obtained. After parallel-to-serial conversion in 360_1 (and frequency up-conversion, not shown), the signal $S^m(t)$ carrying the MC-CDMA symbol is transmitted by the antenna 370_m .

As described further below, the SFTF vectors \mathbf{w}_k^* , $k=1,..,K$, or equivalently the weighting coefficients $w_k^*(\ell, m)$, $\ell=1,..,L$; $m=1,..,M$ are determined by a calculation module 380 from estimates of the coefficients of the downlink transmission channels and supplied to the parallel multipliers 330₁,..,330_K. It is 5 assumed in the following that the transmission is free from inter-carrier interference and inter-symbol interference (the latter, thanks to prefix insertion). In such instance, the downlink transmission channel between antenna m of the base station and the mobile terminal of user k can be characterised by a single multiplicative complex coefficient $h_k(\ell, m)$ (hereinafter called channel coefficient) for each subcarrier ℓ . The 10 coefficients $h_k(\ell, m)$ are assumed identical for the downlink and the uplink channels, assumption which is verified in practice when the MC-CDMA system operates in TDD (Time Division Duplex) mode. The estimates of the channel coefficients are hereinafter denoted $\hat{h}_k(\ell, m)$.

The channel coefficients $h_k(\ell, m)$ depend on the spatial signature of the 15 downlink multipath channel and the fading coefficient of the channel. The spatial signature of the channel (supposed identical for downlink and uplink) is defined by the directions of transmission of the signal to user k or, equivalently by the direction of arrival (DOAs) of the signal transmitted by user k to the base station. It should be understood that the coefficients $h_k(\ell, m)$ for a given user k reflect not only the 20 directivity pattern of the (transmit or receive) beam for this user at the various subcarrier frequencies but also the fading of the transmission channel at these frequencies.

If we now consider a mobile terminal of a given user g having the structure 25 illustrated in Fig. 2 and receiving a signal transmitted by the MC-CDMA of Fig. 3, the decision variable can be expressed as, similar to (4):

$$\hat{d}_g = \sum_{k=1}^K d_k \cdot \sqrt{P_{t_k}} \cdot \sum_{m=1}^M \sum_{\ell=1}^L w_k^*(\ell, m) \cdot h_g(\ell, m) \cdot q_g(\ell) \cdot c_k(\ell) \cdot c_g^*(\ell) + \sum_{\ell=1}^L q_g(\ell) \cdot c_g^*(\ell) \cdot n_g(\ell) \quad (8)$$

which can be reformulated as follows:

$$\begin{aligned}
\hat{d}_g = & d_g \cdot \sqrt{P t_g} \left(\sum_{m=1}^M \sum_{\ell=1}^L h_g(\ell, m) \cdot w_g^*(\ell, m) \cdot c_g(\ell) \cdot e_g^*(\ell) \right) \\
& + \sum_{m=1}^M \sum_{\ell=1}^L h_g(\ell, m) \cdot e_g^*(\ell) \left(\sum_{\substack{k=1 \\ k \neq g}}^K d_k \cdot \sqrt{P t_k} \cdot w_k^*(\ell, m) \cdot c_k(\ell) \right) + \sum_{\ell=1}^L e_g^*(\ell) \cdot n_g(\ell)
\end{aligned} \tag{9}$$

where $n_g(\ell)$ are Gaussian noise samples relative to the different carriers and
5 $e_g(\ell) = q_g^*(\ell) c_g(\ell)$ where the coefficients $q_g(\ell)$ are not necessarily determined by one of
the equalising methods recited above and can take any value. It should be noted that
10 $e_g(\ell)$ are the conjugates of the coefficients combining the components carried by the
different subcarriers at the output of the FFT module 220_g . As it will be apparent to
the man skilled in the art, the first term of expression (9) corresponds to the desired
signal, the second term corresponds to the multiple access interference and the final
term corresponds to the residual noise after despreading.

The expression (9) can be equivalently formulated in a more concise form:

$$15 \quad \hat{d}_g = \tilde{\mathbf{e}}_g^H \cdot (\mathbf{h}_g \circ \mathbf{w}_g^* \circ \tilde{\mathbf{c}}_g) \cdot d_g \cdot \sqrt{P t_g} + \tilde{\mathbf{e}}_g^H \cdot (\mathbf{h}_g \circ \left(\sum_{\substack{k=1 \\ k \neq g}}^K (\mathbf{w}_k^* \circ \tilde{\mathbf{c}}_k) d_k \cdot \sqrt{P t_k} \right) + \mathbf{e}_g^H \cdot \mathbf{n}_g \tag{10}$$

where the boldface letters represent vectors and:

$\tilde{\mathbf{c}}_k$ is a vector of size $M \cdot L$ defined as $\tilde{\mathbf{c}}_k = (\mathbf{c}_k^T, \mathbf{c}_k^T, \dots, \mathbf{c}_k^T)^T$ i.e. is the concatenation of M
20 times the vector $\mathbf{c}_k = (c_k(1), \dots, c_k(L))^T$ representing the spreading sequence for user k ;

$\tilde{\mathbf{e}}_g$ is a vector of size $M \cdot L$ defined as $\tilde{\mathbf{e}}_g = (\mathbf{e}_g^T, \mathbf{e}_g^T, \dots, \mathbf{e}_g^T)^T$ i.e. is the concatenation of M
times the vector $\mathbf{e}_g = (e_g(1), \dots, e_g(L))^T$, or, equivalently, $\tilde{\mathbf{e}}_g = \tilde{\mathbf{c}}_g \circ \tilde{\mathbf{q}}_g$ where
 $\tilde{\mathbf{q}}_g = (\mathbf{q}_g^T, \mathbf{q}_g^T, \dots, \mathbf{q}_g^T)^T$ is the concatenation of M times the vector $\mathbf{q}_g = (q_g(1), \dots, q_g(L))^T$.

25 \mathbf{h}_g is a vector of size $M \cdot L$ defined as $\mathbf{h}_g = (h_g(1,1), \dots, h_g(L,1), \dots, h_g(1,M), \dots, h_g(L,M))^T$
the first L elements of which corresponding to the channel between antenna 1 and

user g , the second L elements of which corresponding to the channel between antenna 2 and user g and so on;

5 \mathbf{w}_k^* is the SFTF vector relative to user k as defined above;

10 \mathbf{e}_g and \mathbf{n}_g are respectively defined as $\mathbf{e}_g = (e_g(1), \dots, e_g(L))^T$ and $\mathbf{n}_g = (n_g(1), \dots, n_g(L))^T$;

15 $(\cdot)^H$ denotes the hermitian transpose operator, $\mathbf{u} \cdot \mathbf{v}$ denotes the scalar product of vectors \mathbf{u} and \mathbf{v} , $\mathbf{u} \circ \mathbf{v}$ denotes the element wise product of vectors \mathbf{u} and \mathbf{v} , i.e. the i^{th} element of vector $\mathbf{u} \circ \mathbf{v}$ is the product of the i^{th} element of vector \mathbf{u} and the i^{th} element of vector \mathbf{v} .

20 According to a first advantageous aspect of the invention, for a given user g , a set of weighting coefficients $w_g^*(\ell, m)$, $\ell = 1, \dots, L$; $m = 1, \dots, M$ (or equivalently a SFTF vector \mathbf{w}_g^*) is determined to ensure a minimisation of the MAI affecting the user in question, taking into account the global effect resulting from the MAI reduction induced by the separation of the active users in the space domain and the MAI increase induced by the loss of orthogonality in the frequency domain.

25 According to a second advantageous aspect of the invention, there is performed a joint MAI minimisation criterion taking into account all the active users. More precisely, the proposed minimisation criterion is not aimed at merely minimising the MAI affecting the reception of a given active user irrespective of the MAI affecting the reception of the other active users but takes also into account the MAIs affecting the latter users induced by the signal transmitted to the user in question.

30 According to a third advantageous aspect of the invention, there is used a MAI minimisation criterion taking into account the transmit power constraint of the MC-CDMA transmitter, which is itself inherently limited by the total transmit power of the base station.

35 In order to explain in further detail the transmission method according to the invention, we consider first a criterion based on the maximisation of the signal to interference plus noise ratio (SINR) relative to a given active user g , under the constraint of a fixed transmit power level for this user.

The signal to interference plus noise ratio relative to the user g can be expressed as:

$$SINR_g = \frac{P_g}{MAI_g + \sigma^2} \quad (11)$$

5

where P_g is the power of the desired signal received by user g , MAI_g is the MAI level affecting the desired signal and σ^2 is variance of the residual noise after despreading.

From the first term of (10) and assuming that the average power of the symbols d_g is unity, the power of the desired signal received by user g can be expressed as:

$$P_g = Pt_g \left| \mathbf{w}_g^H \cdot (\tilde{\mathbf{e}}_g^* \circ \mathbf{h}_g \circ \tilde{\mathbf{c}}_g) \right|^2 \quad (12)$$

From the second term of (10) and assuming that the average power of the symbols d_k is unity, the multiple access interference level MAI_g can be expressed as:

$$MAI_g = \sum_{\substack{k=1 \\ k \neq g}}^K Pt_k \cdot p_{MAI}(k \rightarrow g) \quad (13)$$

where $p_{MAI}(k \rightarrow g)$ reflects the normalised contribution of (the signal transmitted to) user k to the MAI affecting user g and is defined as:

$$p_{MAI}(k \rightarrow g) = \mathbf{w}_k^H \mathbf{v}_{gk} \mathbf{v}_{gk}^H \mathbf{w}_k \quad (14)$$

where $\mathbf{v}_{gk} = \tilde{\mathbf{e}}_g^* \circ \mathbf{h}_g \circ \tilde{\mathbf{c}}_k = \tilde{\mathbf{c}}_g^* \circ \tilde{\mathbf{q}}_g \circ \mathbf{h}_g \circ \tilde{\mathbf{c}}_k$.

25

From (12), (13) and (14), the signal to interference plus noise ratio relative to user g can be rewritten:

$$SINR_g = \frac{Pt_g \left| \mathbf{w}_g^H \cdot (\tilde{\mathbf{e}}_g^* \circ \mathbf{h}_g \circ \tilde{\mathbf{c}}_g) \right|^2}{\sum_{\substack{k=1 \\ k \neq g}}^K Pt_k \cdot \mathbf{w}_k^H \mathbf{v}_{kg} \mathbf{v}_{kg}^H \mathbf{w}_k + \sigma^2} \quad (15)$$

As it is apparent from (15), the expression of $SINR_g$ does not depend only upon the weighting coefficients $w_g^*(\ell, m)$ relative to user g (i.e. the SFTF vector \mathbf{w}_g^* relative to user g) but also upon the weighting coefficients relative to the other users $k \neq g$ (i.e. the SFTF vectors \mathbf{w}_k^* relative to the users $k \neq g$). This can be attributed to the fact that the MAI affecting user g is influenced by the distribution in space and frequency of the signals transmitted to the other users $k \neq g$. In other words, a change of the SFTF vector relative to a given user modifies the SINRs of all the other active users. It follows that the problem of finding the SFTF vector \mathbf{w}_g^* maximising the $SINR_g$ cannot be solved independently of the problem of finding the other SFTF vector \mathbf{w}_k^* maximising the values $SINR_k$ for $k \neq g$. However, finding the set of the SFTF vectors \mathbf{w}_k^* maximising simultaneously all the values $SINR_k$ is a very complex if not intractable task.

According to the invention, the problem of maximising the $SINR_g$ is elegantly solved by observing that in practice the channel response vectors \mathbf{h}_k , $k=1, \dots, K$ have the same statistical properties and that consequently for two given users k and k' the normalised interference contributions $p_{MAI}(k \rightarrow k')$ and $p_{MAI}(k' \rightarrow k)$ can be considered equal, which is especially justified when the same method of space-time filtering is applied to all the users.

More precisely, there is proposed a criterion based upon a pseudo signal to noise plus interference ratio denoted $SINR_g^m$ and defined as follows:

$$SINR_g^m = \frac{P_g}{MAI_g^m + \sigma^2} \quad (16)$$

25

where $MAI_g^m = \sum_{\substack{k=1 \\ k \neq g}}^K Pt_k \cdot p_{MAI}(g \rightarrow k)$ with $p_{MAI}(g \rightarrow k) = \mathbf{w}_g^H \mathbf{v}_{kg} \mathbf{v}_{kg}^H \mathbf{w}_g$, that is:

$$MAI_g^m = \mathbf{w}_g^H \left(\sum_{\substack{k=1 \\ k \neq g}}^K P t_k \cdot \mathbf{v}_{kg} \mathbf{v}_{kg}^H \right) \mathbf{w}_g = \mathbf{w}_g^H \Phi_g \mathbf{w}_g \quad \text{where } \Phi_g \text{ is the quadratic matrix}$$

$$\text{defined as : } \Phi_g = \sum_{\substack{k=1 \\ k \neq g}}^K P t_k \cdot \mathbf{v}_{kg} \mathbf{v}_{kg}^H.$$

The pseudo signal to noise plus interference ratio can therefore be
5 reformulated as:

$$SINR_g^m = \frac{P t_g \left| \mathbf{w}_g^H \cdot (\tilde{\mathbf{e}}_g^* \circ \mathbf{h}_g \circ \tilde{\mathbf{c}}_g) \right|^2}{\mathbf{w}_g^H \Phi_g \mathbf{w}_g + \sigma^2} \quad (17)$$

10 For a fixed predetermined transmit power value $P t_g$, the constraint on the
transmit power for user g can be expressed as a constraint on the module of the SFTF
vector \mathbf{w}_g , namely $\mathbf{w}_g^H \cdot \mathbf{w}_g = 1$.

From (17), the maximisation of $SINR_g^m$ under the constraint of a fixed transmit
power is equivalent to find :

$$15 \quad \arg \max \frac{P t_g \left| \mathbf{w}_g^H \cdot (\tilde{\mathbf{e}}_g^* \circ \mathbf{h}_g \circ \tilde{\mathbf{c}}_g) \right|^2}{\mathbf{w}_g^H (\Phi_g + \sigma^2 \mathbf{I}_{ML}) \mathbf{w}_g} \quad (18)$$

under the constraint $\mathbf{w}_g^H \cdot \mathbf{w}_g = 1$, where \mathbf{I}_{ML} is the identity matrix of size $M.L \times M.L$.

It should be noted that expression (18) depends only on the SFTF vector \mathbf{w}_g and
20 is invariant by multiplication of \mathbf{w}_g with a constant. Defining $\tilde{\mathbf{w}}_g = \beta \mathbf{w}_g$, where β is
a scalar, it is therefore possible to look for the optimal vector $\tilde{\mathbf{w}}_g$ that verifies
 $\tilde{\mathbf{w}}_g^H (\tilde{\mathbf{e}}_g^* \circ \mathbf{h}_g \circ \tilde{\mathbf{c}}_g) = 1$, and then to normalise the result by the factor $\frac{1}{\|\tilde{\mathbf{w}}_g\|}$ in order to
obtain \mathbf{w}_g . The optimum pre-distortion vector SFTF $\tilde{\mathbf{w}}_g$ must therefore satisfy:

$$25 \quad \arg \min \left(\tilde{\mathbf{w}}_g^H \Psi_g \tilde{\mathbf{w}}_g \right) \quad \text{with } \Psi_g = \Phi_g + \sigma^2 \mathbf{I}_{ML} \quad \text{and} \quad \tilde{\mathbf{w}}_g^H (\tilde{\mathbf{e}}_g^* \circ \mathbf{h}_g \circ \tilde{\mathbf{c}}_g) = 1 \quad (19)$$

For solving this problem, we introduce the Lagrange function:

$$\mathcal{L} = \tilde{\mathbf{w}}_g^H \mathbf{\Psi}_g \tilde{\mathbf{w}}_g - \lambda (\tilde{\mathbf{w}}_g^H \mathbf{f}_g - 1) \text{ with } \mathbf{f}_g = \tilde{\mathbf{e}}_g^* \circ \mathbf{h}_g \circ \tilde{\mathbf{c}}_g \quad (20)$$

5

where λ is a Lagrange multiplier.

By calculating the gradient according to the vectors $\tilde{\mathbf{w}}_g^*$ (the same result can be obtained by calculating the gradient according to the vector $\tilde{\mathbf{w}}_g$) :

$$10 \quad \nabla_{\tilde{\mathbf{w}}_g} \mathcal{L} = \mathbf{\Psi}_g \tilde{\mathbf{w}}_g - \lambda \mathbf{f}_g = 0 \quad (21)$$

Finally, we can conclude that the optimal SFTF vector $\tilde{\mathbf{w}}_g$ is given by :

$$15 \quad \tilde{\mathbf{w}}_g = \lambda (\mathbf{\Phi}_g + \sigma^2 \mathbf{I}_{ML})^{-1} \mathbf{f}_g = \lambda (\mathbf{\Phi}_g + \sigma^2 \mathbf{I}_{ML})^{-1} (\tilde{\mathbf{e}}_g^* \circ \mathbf{h}_g \circ \tilde{\mathbf{c}}_g) \quad (22)$$

The SFTF vector \mathbf{w}_g can be obtained from $\tilde{\mathbf{w}}_g$:

$$20 \quad \mathbf{w}_g = \mu_g (\mathbf{\Phi}_g + \sigma^2 \mathbf{I}_{ML})^{-1} (\tilde{\mathbf{c}}_g^* \circ \tilde{\mathbf{q}}_g \circ \mathbf{h}_g \circ \tilde{\mathbf{c}}_g) \quad (23)$$

where the coefficient μ_g is given by the constraint upon the transmit power for user g , namely is chosen so that $\mathbf{w}_g^H \mathbf{w}_g = 1$.

In practice, the downlink channel coefficients $h_g(\ell, m)$ constituting the vector \mathbf{h}_g are assumed identical to the corresponding uplink channel coefficients, which are in turn estimated from pilot symbols transmitted from the active users to the base station.

25 Turning back to Fig. 3 and denoting $\hat{\mathbf{h}}_k$ the vector of the estimates $\hat{h}_k(\ell, m)$, the calculation module 380 determines for each active user k the SFTF vector \mathbf{w}_k from:

$$20 \quad \mathbf{w}_k = \mu_k (\hat{\mathbf{\Phi}}_k + \sigma^2 \mathbf{I}_{ML})^{-1} (\tilde{\mathbf{c}}_k^* \circ \tilde{\mathbf{q}}_k \circ \hat{\mathbf{h}}_k \circ \tilde{\mathbf{c}}_k) \quad (24)$$

30 where the coefficient μ_k is given by the constraint upon the transmit power for user k (i.e. $\mathbf{w}_k^H \mathbf{w}_k = 1$) and

$$\hat{\Phi}_k = \sum_{\substack{k=1 \\ k \neq k}}^K P t_k \hat{\mathbf{v}}_{kk} \hat{\mathbf{v}}_{kk}^H \quad \text{with} \quad \mathbf{v}_{kk} = \tilde{\mathbf{c}}_k^* \circ \tilde{\mathbf{q}}_k \circ \hat{\mathbf{h}}_k \circ \tilde{\mathbf{c}}_k \quad (25)$$

According to first embodiment of the invention, the SFTF vector \mathbf{w}_g^* for a given user g is determined by the calculation module 380 from:

5

$$\mathbf{w}_g = \mu_g (\hat{\Phi}_g + \sigma^2 \mathbf{I}_{ML})^{-1} (\tilde{\mathbf{c}}_g^* \circ \hat{\mathbf{h}}_g \circ \tilde{\mathbf{c}}_g) \quad (26)$$

which can be further simplified if the spreading sequences are such that $c_g(\ell) \cdot c_g^*(\ell) = 1$ for $\ell = 1, \dots, L$ e.g. if Walsh-Hadamard spreading sequences (10) ($c_g(\ell) \in \{-1, 1\}$) are used:

$$\mathbf{w}_g = \mu_g (\hat{\Phi}_g + \sigma^2 \mathbf{I}_{ML})^{-1} \hat{\mathbf{h}}_g \quad (27)$$

In such instance, the receiving process carried out at the mobile terminals can be drastically simplified as shown in Fig. 4. The MC-CDMA receiver for a user g is schematically represented in Fig. 4 and comprises modules 410_g to 450_g identical to the corresponding modules 210_g to 250_g of Fig. 2. However, in contrast with the MC-CDMA receiver of the prior art (Fig. 2), a simple despreading is effected at the output of the FFT module 420_g and no equalisation is required anymore. In particular, an estimation of the downlink channel coefficients is not needed at the receiver side, thus relieving the mobile terminal of the computation burden associated therewith.

It should be appreciated that the filtering in the frequency domain performed at the transmission side by the weighting coefficients of SFTF vector \mathbf{w}_g^* fully or almost fully pre-compensates for the fading on the carriers of the downlink transmission channel.

According to a second embodiment of the invention, the downlink channel coefficients $h_g(\ell, m)$ are coarsely estimated by the MC-CDMA transmitter and a complementary equalisation is performed at the receiving side.

This is for example the case if the estimates of the uplink channel coefficients (from which the latter are derived) are updated at a rate lower than the actual variation thereof. More specifically, denoting $\hat{\mathbf{h}}_g^C$ the vector representing the coarse estimates of

the channel coefficients for a given user g , the MC-CDMA transmitter would apply a SFTF filtering based on:

$$\mathbf{w}_g = \mu_g (\hat{\Phi}_g + \sigma^2 \cdot \mathbf{I}_{ML})^{-1} (\tilde{\mathbf{c}}_g^* \circ \hat{\mathbf{h}}_g^C \circ \tilde{\mathbf{c}}_g) \quad (28)$$

5

and a set of equalising coefficients $q_g^f(\ell), \ell = 1,..L$ would finely compensate for the residual frequency distortion at the receiving side.

In a further variant, the vector of coarse estimates, $\hat{\mathbf{h}}_g^C$, used for determining 10 \mathbf{w}_g^* in the calculation module 380, is derived from the spatial signature of user g . More specifically, it is assumed that the channel coefficients $h_g(\ell, m)$ can be decomposed into :

$$h_g(\ell, m) = \bar{h}_g(\ell, m) \eta_g(\ell) \quad (29)$$

15

where $\bar{h}_g(\ell, m)$ accounts for the spatial signature of user g (varying relatively slowly in time) and $\eta_g(\ell)$ accounts for the frequency fading of the channel. The MC-CDMA transmitter estimates the coefficients $\bar{h}_g(\ell, m)$ from the DOAs of the signal received by the antenna array from user g and uses these estimates $\hat{\bar{h}}_g(\ell, m)$ as elements of the 20 vector $\hat{\mathbf{h}}_g^C$.

Fig. 5 shows schematically a receiver for use with a MC-CDMA transmitter according to the latter variant. The modules 510_g to 550_g are identical to the corresponding modules 210_g to 250_g of Fig. 2 and the compensation for the fast fading factors $\eta_g(\ell)$ is ensured here by equalising coefficients $q_g^f(\ell), \ell = 1,..L$ derived from 25 $\eta_g(\ell)$ according to one of the known types of equalisation method.

A further advantageous aspect of the invention lies in the possibility of increasing the capacity of a MC-CDMA system. It is reminded that the capacity of a conventional MC-CDMA system is limited by the number of available spreading 30 codes (or spreading sequences), which is equal to the number L of subcarriers when the codes are chosen orthogonal. The user separation in the space domain provided by the transmission method according to the invention allows to reuse the same spreading

codes for different users. More specifically, a spreading code $c_k(\ell), \ell=1,..,L$ already allocated to a user k can be also reallocated to a user k' provided users k and k' have substantially different spatial signatures.

5 According to a first possible allocation scheme, if the number of active users happens to exceed the number L of available spreading codes (for example, if the available spreading codes are already allocated and if an incoming call is requested), the spreading codes are reallocated *e.g.* in the natural order $\mathbf{c}_1, \mathbf{c}_2, \dots$, so that two users k and $k+L$ share the same spreading code \mathbf{c}_k . In order to reduce the interference

10 occurring when users k and $k+L$ exhibit similar spatial signatures, it is further proposed to apply random scrambling codes on top of the available spreading codes. More specifically, if a symbol has to be transmitted to a user k belonging to a given set Ω_p , where $p \in \{1,..,P\}$, it is multiplied by the following sequence:

15 $c_k^{ext}(\ell) = c_{k[L]}(\ell) m_p(\ell), \ell=1,..,L$ (30)

where user index k may be greater than L , p denotes the integer part of the division k/L and $k[L]$ denotes the rest thereof, $c_k^{ext}(\ell), \ell=1,..,L$ stands for a spreading sequence belonging to an extended set (of cardinal $L.P$) and $m_p(\ell), \ell=1,..,L$ is a random scrambling code.

Since users belonging to a given set Ω_p are subjected to the same scrambling code, their respective spreading sequences (as defined in (30)) are orthogonal and, consequently, these users are spatially and frequency separated by the transmission method according to the invention. In contrast, orthogonality is not maintained between spreading sequences allocated to users belonging to different sets. However, the latter users still benefit from the spatial separation provided by said transmission method as well as from the interference reduction due to the random scrambling .

30 Although the MC-CDMA transmitter illustrated in Fig. 3 has been described in terms of functional modules *e.g.* computing or estimating means, it will be appreciated by the man skilled in the art that all or part of this device can be implemented by means of a single processor either dedicated for performing all the functions depicted or in the form of a plurality of processors either dedicated or programmed for each performing one or some of said functions.
